# GLM review

# Components of GLM

- **Random component** specifies the conditional distribution for the response variable
  - doesn't have to be normal
  - can be any distribution in the “exponential” family of distributions
- **Systematic component** specifies linear function of predictors (linear predictor)
- **Link** [denoted by  $g(\cdot)$ ] specifies the relationship between the expected value of the random component and the systematic component
  - can be linear or nonlinear

# Logistic Regression as GLM

- **The model:**

$$\begin{aligned}\text{Logit}(P(x)) &= \log\left(\frac{P(x)}{1 - P(x)}\right) \\ &= \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + \dots + \beta_p x_{pi}\end{aligned}$$

- **Random component:**  $y_i$  follows a Binomial distribution (outcome is a binary variable)
- **Systematic component:** linear predictor

$$\beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + \dots + \beta_p x_{pi}$$

- **Link function:** *logit* (log of the odds that the event occurs)

$$g(P(x)) = \text{logit}(P(x)) = \log\left(\frac{P(x)}{1 - P(x)}\right)$$

# Additive vs. multiplicative models

- 1 Linear regression is an *additive* model
  - e.g. for two binary variables  $\beta_1 = 1.5$ ,  $\beta_2 = 1.5$ .
  - If  $x_1 = 1$  and  $x_2 = 1$ , this adds 3.0 to  $E(y|x)$
- 2 Logistic regression is a *multiplicative* model
  - It is additive on *log*-odds scale
  - If  $x_1 = 1$  and  $x_2 = 1$ , this adds 3.0 to  $\log(\frac{P}{1-P})$
  - Odds-ratio  $\frac{P}{1-P}$  increases 20-fold:  $\exp(1.5 + 1.5)$  or  $\exp(1.5) * \exp(1.5)$

# **Interpretation of main effects and interactions in logistic regression**

# Motivating example: contraceptive use data

outline

GLM review

Interpretation  
of main  
effects and  
interactions in  
logistic  
regression

**The Design  
Matrix**

# The Design Matrix

# What is the design matrix, and why?

- 1 **What?** The design matrix is the most generic, flexible way to specify them
- 2 **Why?** There are multiple possible and reasonable regression models for a given study design.

# Matrix notation for the multiple linear regression model

$$\begin{pmatrix} Y_1 \\ Y_2 \\ \vdots \\ Y_N \end{pmatrix} = \begin{pmatrix} 1 & x_1 \\ 1 & x_2 \\ \vdots & \\ 1 & x_N \end{pmatrix} \begin{pmatrix} \beta_0 \\ \beta_1 \end{pmatrix} + \begin{pmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \vdots \\ \varepsilon_N \end{pmatrix}$$

or simply:

$$\mathbf{Y} = \mathbf{X}\beta + \varepsilon$$

- The design matrix is  $\mathbf{X}$
- the computer will take  $\mathbf{X}$  as a given when solving for  $\beta$  by minimizing the sum of squares of residuals  $\varepsilon$ , or maximizing likelihood.

# Choice of design matrix

- The model formula encodes a default model matrix, e.g.:

```
group <- factor( c(1, 1, 2, 2) )  
model.matrix(~ group)
```

```
##      (Intercept) group2  
## 1              1      0  
## 2              1      0  
## 3              1      1  
## 4              1      1  
## attr(,"assign")  
## [1] 0 1  
## attr(,"contrasts")  
## attr(,"contrasts")$group  
## [1] "contr.treatment"
```

# Choice of design matrix (cont'd)

What if we forgot to code group as a factor?

```
group <- c(1, 1, 2, 2)
model.matrix(~ group)
```

```
##      (Intercept) group
## 1             1      1
## 2             1      1
## 3             1      2
## 4             1      2
## attr(,"assign")
## [1] 0 1
```
